To effectively treat coronary disease, we need to have an objective, dynamic, clinically useful method for quantifying blood flow in the coronary artery. Currently, there is no clinically available way to measure the instantaneous flow of blood in an artery. Despite the obvious importance of this technology, the development of this technology has been frustratingly slow. Clinical safety concerns, coupled with the development of methods for measuring blood velocity and blood flow have prevented the development of this technology. We propose to develop a minimally invasive, clinically useful and safe method for high-resolution assessment of instantaneous, real-time blood flow in arteries. Our approach relies on a novel method for optical Doppler velocimetry (ODV). ODV is a clinically- and FDA-approved method for non-invasive, continuous, continuous imaging of blood velocities in vivo. ODV images blood flow, with frequencies ranging from 1-200 Hz, with high resolution and high signal-to-noise ratios. We have recently demonstrated that a velocity-encoded ODV signal acquired at a limited number of rotation angles can be converted into a blood-flow signal with high spatial resolution. Importantly, we have also shown that continuous ODV imaging of the coronaries can be performed without myocardial wall motion artifacts. However, in our current approach, only a very limited number of measurements can be used. Our goal is to develop a new and novel method for high-resolution imaging of blood flow, taking advantage of recent technological advances in Doppler radar for pulsed Doppler ultrasound. Specifically, we propose to develop a new, more sensitive, less intermittent waveform, based on the flexible and fast-
